Outline

Rev: # 8d7fc39ab521

Outline

What are the rules that determine the capabilities that a process has in a given user namespace?

User namespace hierarchies

- User NSs exist in a hierarchy
  - Each user NS has a parent, going back to initial user NS
- Parental relationship is established when user NS is created:
  - *clone()*: parent of new user NS is NS of caller of *clone()*
  - *unshare()*: parent of new user NS is caller's previous NS
- Parental relationship is significant because it plays a part in determining capabilities a process has in user NS

User namespaces and capabilities

- Whether a process has an effective capability inside a "target" user NS depends on several factors:
  - Whether the capability is present in process's effective set
  - Which user NS the process is a member of
  - The process's effective UID
  - The effective UID of process that created target user NS
  - The parental relationship between process's user NS and target user NS
- See also `namespaces/ns_capable.c`
  - (A program that encapsulates the rules described next)

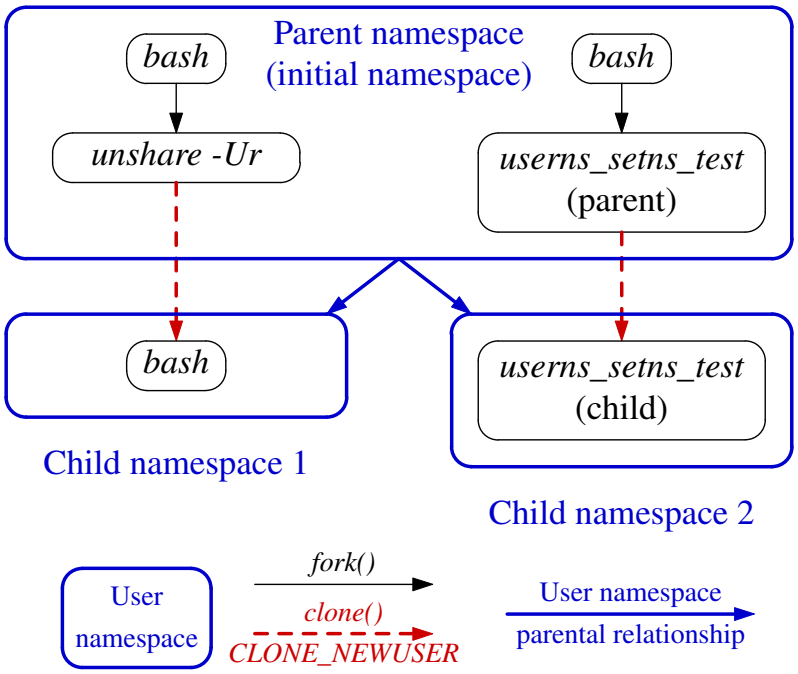
Capability rules for user namespaces

1. A process has a capability in a user NS if:
   - it is a **member of the user NS**, and
   - **capability is present in its effective set**
   - Note: this rule doesn't grant that capability in parent NS
2. A process that has a capability in a user NS **has the capability in all descendant user NSs** as well
   - I.e., members of user NS are not isolated from effects of privileged process in parent/ancestor user NS
3. A **process in a parent user NS that has same eUID as eUID of creator of user NS** has all capabilities in the NS
   - At creation time, **kernel records eUID of creator** as "owner" of user NS
   - By virtue of previous rule, process also has capabilities in all descendant user NSs

Outline

Demonstration of capability rules

Set up following scenario; then both `userns_setns_test` processes will try to join *Child namespace 1* using *setns()*



namespaces/userns_setns_test.c

```
./userns_setns_test /proc/PID/ns/user
```

- Creates a child process in a new user NS
- Parent and child then both call *setns()* to attempt to join user NS identified by argument
  - *setns()* requires `CAP_SYS_ADMIN` capability in target NS

namespaces/userns_setns_test.c

```
int main(int argc, char *argv[]) {
    ...
    long fd = open(argv[1], O_RDONLY);

    pid_t child_pid = clone(childFunc, stack + STACK_SIZE,
                            CLONE_NEWUSER | SIGCHLD, (void *) fd);
    test_setns("parent: ", fd);
    printf("\n");

    waitpid(child_pid, NULL, 0);
    exit(EXIT_SUCCESS);
}
```

- Open `/proc/PID/ns/user` file specified on command line
- Create child in new user NS
  - *childFunc()* receives file descriptor as argument
- Try to join user NS referred to by *fd* (*test_setns()*)
- Wait for child to terminate

namespaces/userns_setns_test.c

```
static int childFunc(void *arg) {
    long fd = (long) arg;

    usleep(100000);
    test_setns("child: ", fd);
    return 0;
}
```

- Child sleeps briefly, to allow parent's output to appear first
- Child attempts to join user NS referred to by *fd*

namespaces/userns_setns_test.c

```
static void display_symlink(char *pname, char *link) {
    char target[PATH_MAX];
    ssize_t s = readlink(link, target, PATH_MAX);
    printf("%s%s ==> %.*s\n", pname, link, (int) s, target);
}

static void test_setns(char *pname, int fd) {
    display_symlink(pname, "/proc/self/ns/user");
    display_creds_and_caps(pname);
    if (setns(fd, CLONE_NEWUSER) == -1) {
        printf("%s setns() failed: %s\n", pname, strerror(errno));
    } else {
        printf("%s setns() succeeded\n", pname);
        display_symlink(pname, "/proc/self/ns/user");
        display_creds_and_caps(pname);
    }
}
```

- Display caller's user NS symlink, credentials, and capabilities
- Try to *setns()* into user NS referred to by *fd*
- On success, again display user NS symlink, credentials, and capabilities

namespaces/userns_functions.c

```
 1 static void display_creds_and_caps(char *msg) {
 2     printf("%seUID = %ld;  eGID = %ld;  ", msg,
 3             (long) geteuid(), (long) getegid());
 4
 5     cap_t caps = cap_get_proc();
 6     char *s = cap_to_text(caps, NULL)
 7     printf("capabilities: %s\n", s);
 8
 9     cap_free(caps);
10     cap_free(s);
11 }
```

- Display caller's credentials and capabilities
  - (Different source file)

namespaces/userns_setns_test.c

In a terminal in initial user NS, we run the following commands:

```
$ id -u
1000
$ readlink /proc/$$/ns/user
user:[4026531837]
$ PS1='sh2# ' unshare -Ur bash
sh2# echo $$
30623
sh2# id -u
0
sh2# readlink /proc/$$/ns/user
user:[4026532638]
```

- Show UID and user NS for initial shell
- Start a new shell in a new user NS
  - Show PID of new shell
  - Show UID and user NS of new shell

namespaces/userns_setns_test.c

```
$ ./userns_setns_test /proc/30623/ns/user
parent: readlink("/proc/self/ns/user") ==> user:[4026531837]
parent: eUID = 1000; eGID = 1000;  capabilities: =
parent: setns() succeeded
parent: eUID = 0;  eGID = 0;  capabilities: =ep

child:  readlink("/proc/self/ns/user") ==> user:[4026532639]
child:  eUID = 65534; eGID = 65534;  capabilities: =ep
child:  setns() failed: Operation not permitted
```

In a second terminal window, we run our *setns()* test program:

- Results of *readlink()* calls show:
  - Parent `userns_setns_test` process is in initial user NS
  - Child `userns_setns_test` is in another user NS
- *setns()* in parent succeeded, and parent gained full capabilities as it moved into the user NS
- *setns()* in child fails; child has no capabilities in target NS

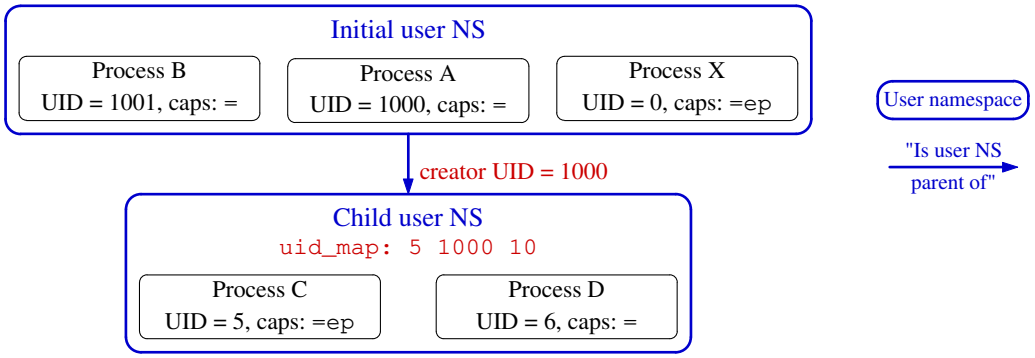
namespaces/userns_setns_test.c

```
$ ./userns_setns_test /proc/30623/ns/user
parent: readlink("/proc/self/ns/user") ==>
        user:[4026531837]
parent: setns() succeeded
parent: eUID = 0;  eGID = 0;  capabilities: =ep

child:  readlink("/proc/self/ns/user") ==>
        user:[4026532639]
child:  setns() failed: Operation not permitted
```

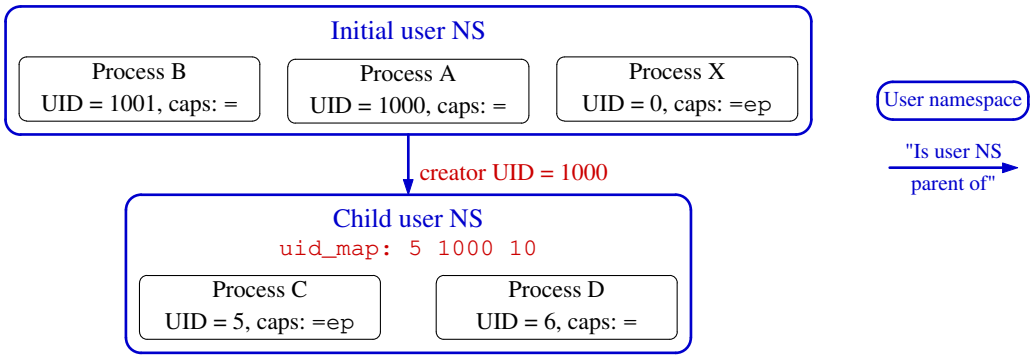
- *setns()* in child failed:
  - Rule 3: "processes in **parent** user NS that have **same eUID** as creator of user NS have all capabilities in the NS"
  - Parent `userns_setns_test` process was in **parent user NS** of target user NS and so had `CAP_SYS_ADMIN`
  - Child `userns_setns_test` process was in **sibling user NS** and so had no capabilities in target user NS

Quiz (who can signal a process in a child user NS?)



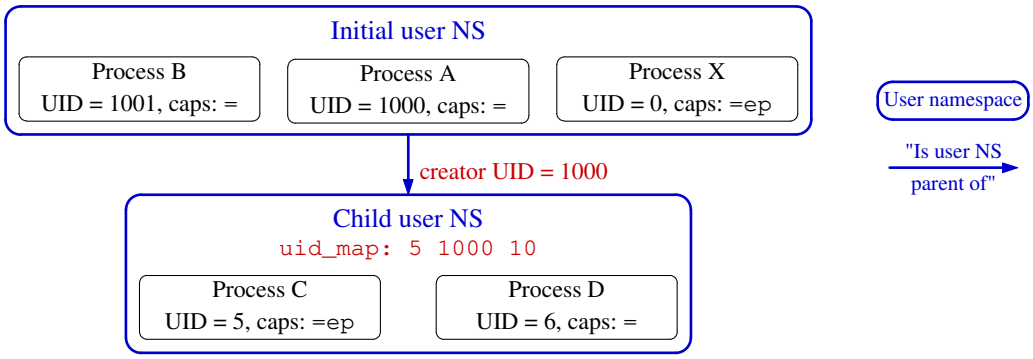
- Child user NS was created by a process with UID 1000
  - That process (which presumably was not A) had capabilities that allowed it to create a user NS with UID map with *length* > 1
- Process X has all capabilities in initial user NS
- Assume process A and process B have no capabilities in initial user NS
- Assume C was first process in child NS and has all capabilities in NS
- Process D has no capabilities

Quiz (who can signal a process in a child user NS?)



- Sending a signal requires UID match or `CAP_KILL` capability
- To which of B, C, D can process A send a signal?
- Can B send a signal to D? Can D send a signal to B?
- Can process X send a signal to processes C and D?
- Can process C send a signal to A? To B?
- Can C send a signal to D?

Quiz (who can signal a process in a child user NS?)



- A can't signal B, but can signal C (matching credentials) and D (because A has capabilities in D's NS)
- B can signal D (matching credentials); likewise, D can signal B
- X can signal C and D (because it has capabilities in parent user NS)
- C can signal A (credential match), but not B
- C can signal D, because it has capabilities in its NS

Outline

Exercises

1. As an unprivileged user, start two *sleep* processes, one as the unprivileged user and the other as UID 0:

```
$ id -u
1000
$ sleep 1000 &
$ sudo sleep 2000
```

As superuser, in another terminal window use *unshare* to create a user namespace (*–U*) with root mappings (*–r*) and run a shell in that namespace:

```
$ SUDO_PS1="ns2# " sudo unshare -U -r bash --norc
```

   - (Root mappings == process's UID and GID in parent NS map to 0 in child NS)
   - Setting the `SUDO_PS1` environment variable causes *sudo(8)* to set the `PS1` environment variable for the command that it executes. (`PS1` defines the prompt displayed by the shell.) The *bash --norc* option prevents the execution of shell start-up scripts that might change `PS1`.

[Exercises continue on next slide]

Exercises

Verify that the shell has a full set of capabilities and a UID map "0 0 1" (i.e., UID 0 in the parent namespace maps to UID 0 in the child user namespace):

```
ns2# grep -E 'Cap(Prm|Eff)' /proc/$$/status
ns2# cat /proc/$$/uid_map
```

From this shell, try to kill each of the *sleep* processes started above:

```
ns2# ps -o 'pid uid cmd' -C sleep   # Discover 'sleep' PIDs
...
ns2# kill -9 <PID-1>
ns2# kill -9 <PID-2>
```

Which of the *kill* commands succeeds? Why?

Exercises

2. Write a program to set up two processes in a child user namespace as in the scenario shown in slide 20-21.
[template: `namespaces/ex.userns_cap_sig_expt.c`]
   - After compiling the program, assign capabilities to the executable as follows:

     ```
     sudo setcap cap_setuid,cap_setgid=pe <program-file>
     ```

   - While running the program, try sending signals to processes "C" and "D" from a shell in the initial user namespace, in order to verify the answers given on slide 20-21.

Outline

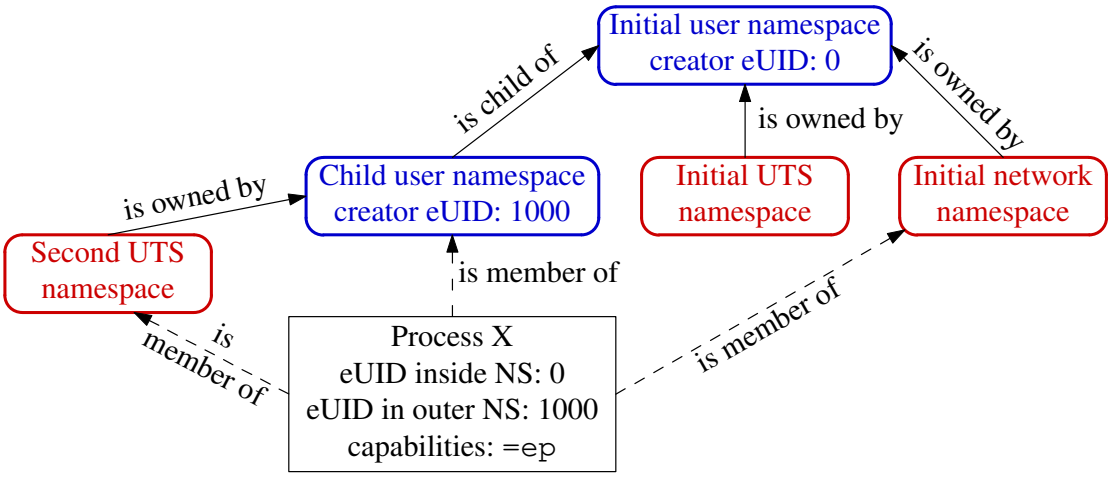
User namespaces and capabilities

- Kernel grants initial process in new user NS a full set of capabilities
- But, those capabilities are available **only for operations on objects governed by the new user NS**

User namespaces and capabilities

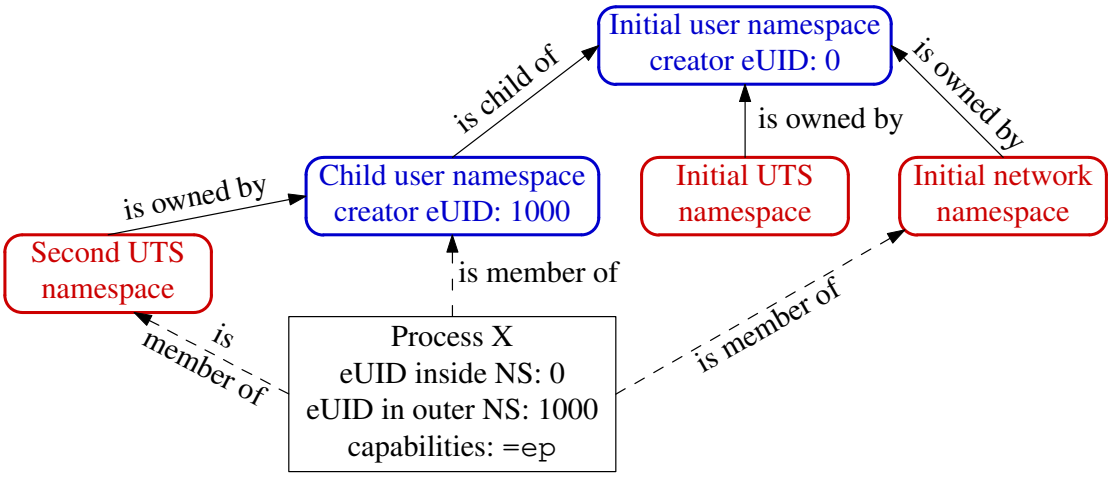
- **Kernel associates each non-user NS instance with a specific user NS instance**
  - Each non-user NS is "owned" by a user NS
  - When creating a new non-user NS, user NS of the creating process becomes the owner of the new NS
- Suppose a process operates on global resources governed by a (non-user) NS:
  - Privilege checks are done according to process's capabilities in user NS that owns the NS
- ⇒ User NSs can deliver full capabilities inside a user NS without allowing capabilities in outer user NS(s)
  - (Barring kernel bugs)

User namespaces and capabilities–an example



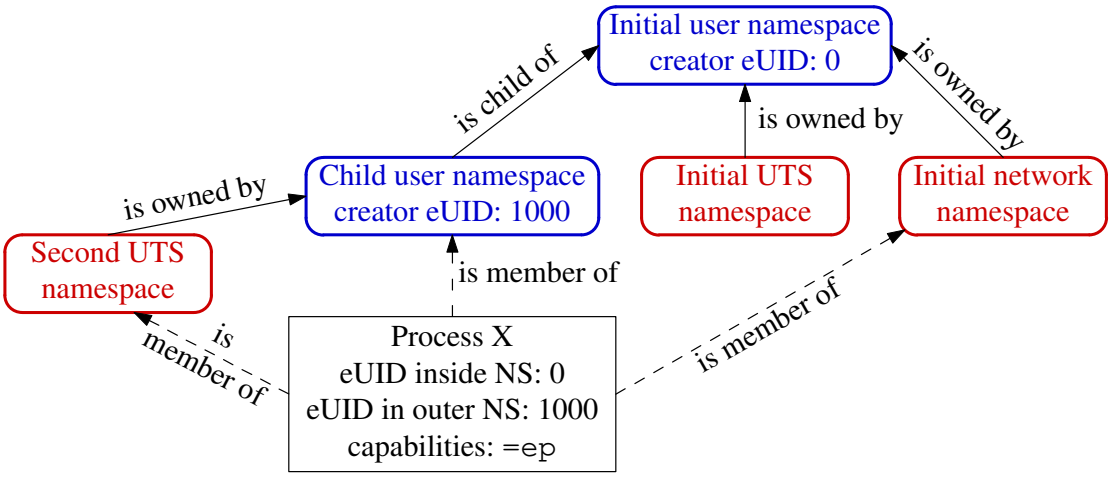
- Example scenario; X was created with: `unshare -Ur -u <prog>`
  - X is in a new user NS, created with root mappings
  - X is in a new UTS NS, which is owned by new user NS
  - X is in initial instance of all other NS types (e.g., network NS)

User namespaces and capabilities–an example



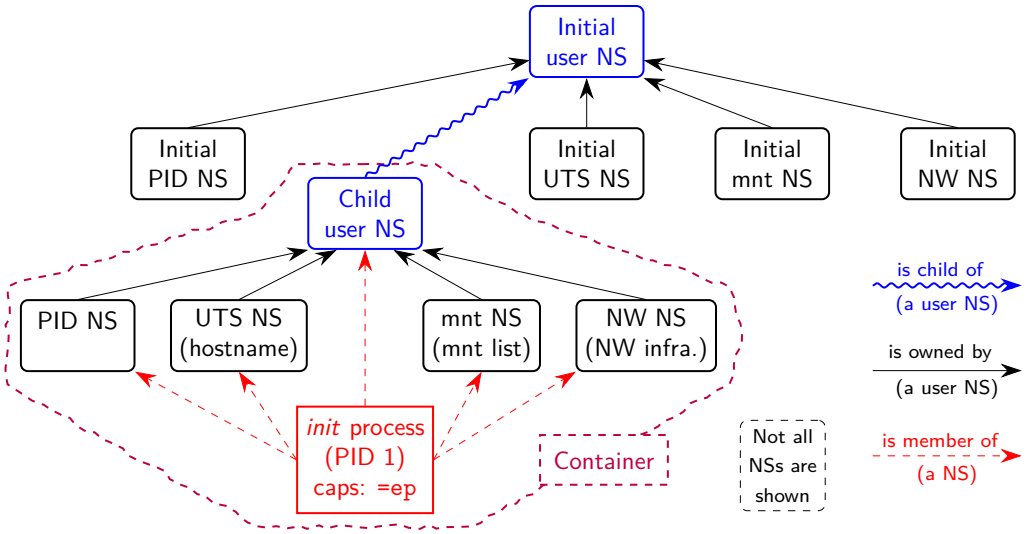
- Suppose X tries to change host name (`CAP_SYS_ADMIN`)
  - E.g., `hostname bienne`
- X is in second **UTS** NS
- Privileges checked according to X's capabilities in user NS that owns that UTS NS ⇒ succeeds (X has capabilities in user NS)

User namespaces and capabilities–an example



- Suppose X tries to bring network device up/down (`CAP_NET_ADMIN`)
  - E.g., `ip link set dev lo down`
- X is in initial **network** NS
- Privileges checked according to X's capabilities in user NS that owns network NS ⇒ attempt fails (no capabilities in initial user NS)

Containers and namespaces



- "Superuser" process in a container has **root power over resources governed by non-user NSs owned by container's user NS**
- And does **not** have privilege in outside user NS
  - (E.g., can't change mounts seen by processes outside container)

Demo: effect of capabilities in a user NS

- Create a shell in new user and UTS NSs:

```
$ unshare -Ur -u bash
# getpcaps $$
929: =ep                # Shell has all capabilities in its user NS
```

- Since this shell has all capabilities in user NS that owns its UTS NS, we can change hostname:

```
# hostname
bienne
# hostname langwied
# hostname
langwied
```

- But, this shell is in a network NS owned by **initial** user NS, and so can't turn a NW device down:

```
# ip link set dev lo down
RTNETLINK answers: Operation not permitted
```

What about resources not governed by namespaces?

- Some privileged operations relate to resources/features not (yet) governed by any namespace
  - E.g., load kernel modules, raise process nice values
- Having all capabilities in a (noninitial) user NS doesn't grant power to perform operations on features not currently governed by any NS
  - E.g., load/unload kernel modules, raise process nice values
  - IOW: to perform these operations, process must have the relevant capability in the **initial** user NS

Outline

Discovering namespace relationships

- To understand how capabilities work in NS, we need to know how NSs are related to each other
  - Which user NS owns a nonuser NS?
  - What is hierarchical relationship of user NSs?
  - Which NS is each process a member of?
- We can discover this info using *ioctl()* operations and `/proc/PID/ns/*` symlinks
- Info can be used to build visualization tools for NSs
  - An example: `namespaces/namespaces_of.go`
  - A better example: `https://github.com/TheDiveO/lxkns`

ioctl() operations for namespaces

```
#include <sys/ioctl.h>
int ioctl(int fd, unsigned long request, ...);
```

- There are *many* *ioctl()* operations...
- Certain *ioctl()* operations can be applied to a file descriptor (FD) that refers to a NS
  - E.g., FD obtained by opening `/proc/PID/ns/*` file
  - Details in *ioctl_ns(2)*
- Some of those operations return a (new) FD that refers to another NS
  - To determine which NS, we use *stat()*/*fstat()*

stat() and *fstat()*

```
#include <sys/stat.h>
int stat(const char *pathname, struct stat *statbuf);
int fstat(int fd, struct stat *statbuf);
```

- The "stat" system calls return metadata from a file inode
- Metadata is returned via *struct stat*, which includes fields:
  - *st_dev*: device ID
  - *st_ino*: inode number
  - Device ID + inode # form **unique identifier for NS**

Comparing namespace identifiers

- To discover NS that a file descriptor refers to, we compare with `/proc/PID/ns/*` symlinks:

```
int fd = ioctl(...);

struct stat sb1, sb2;
fstat(fd, &sb1);
stat(path, &sb2);   // 'path' is a /proc/PID/ns/* symlink

if (sb1.st_dev == sb2.st_dev && sb1.st_ino == sb2.st_ino) {
    // 'fd' and 'path' refer to same NS
}
```

ioctl() operations for namespaces

- `NS_GET_USERNS`: return FD referring to **owning user NS** for NS referred to by *fd*
  - Returned FD can be compared (*fstat()*, *stat()*) with `/proc/PID/ns/user` files to discover owning user NS
- `NS_GET_PARENT`: return FD referring to the **parent namespace** of NS referred to by *fd*
  - Valid only for hierarchical namespaces (PID, user)
  - Returned FD can be compared (*fstat()*, *stat()*) with `/proc/PID/ns/{pid,user}` files to discover parent NS
  - Synonymous with `NS_GET_USERNS` for user namespaces

ioctl() operations for namespaces

- `NS_GET_OWNER_UID`: return **UID of creator of user NS** referred to by *fd*
- `NS_GET_NSTYPE`: return the **type of NS** referred to by *fd*
  - Returns one of `CLONE_NEW*` constants
- Example code:
  - `namespaces/ns_capable.c`
  - `namespaces/namespaces_of.go`
  - `namespaces/pid_namespaces.go`
  - *ioctl_ns(2)*
  - `http://blog.man7.org/2016/12/introspecting-namespace-relationships.html`

`namespaces/namespaces_of.go` example

- `namespaces/namespaces_of.go` shows NS memberships of specified processes, in context of user NS hierarchy
- To demo, we set up scenario shown in earlier diagram:

```
$ echo $$             # PID of a shell in initial user NS
327
$ unshare -Ur -u sh   # Create new user and UTS NSs
# echo $$             # PID of shell in new NSs
353
```

  - Run a shell in new user and UTS NSs
    - That shell will be a member of initial instance of other NSs

Discovering namespace relationships

- Inspect with `namespaces/namespaces_of.go` program:

```
$ go run namespaces_of.go --namespaces=net,uts 327 353
user {4 4026531837} <UID: 0>
        [ 327 ]
    net {4 4026532008}
            [ 327 353 ]
    uts {4 4026531838}
            [ 327 ]
    user {4 4026532760} <UID: 1000>
            [ 353 ]
        uts {4 4026532761}
                [ 353 ]
```

  - Indentation indicates user NS ownership / parental relationship between user NSs
  - Shells are in same network NS, but different UTS NSs
  - Second UTS NS is owned by second user NS
  - NS IDs (`{...}`) include device ID (4) from (hidden) NS filesystem
